

Exercise sheet 5 - Python Basics

Your preparation of exercises should include two aspects:

(1) Try to present exercises in a way that everyone can follow (even if that person didn't do the exercise at all), so please explain all the (vital) parts of your solution in a slow and comprehensive way.

(2) Try to also include some background information where applicable, and/or explain the possible context/motivation for the given exercise.

1. Start a python shell and type

```
import this
```

Explain what you are doing and the result.

2. There are a few ways to run python code, e.g.

- python shell
- ipython
- scripts
- jupyter notebooks

Explain some of the advantages and disadvantages of these methods. In which cases you should use each of them?

3. Create a jupyter notebook and use it to explain the most important python data types (e.g. str, int, float, list, dict, tuple, etc)

- How do you determine the type of a variable?

4. Write a python script that takes 3 numbers as command line arguments, adds them up and prints the result. Access to the command line arguments is provided by the module sys, where `sys.argv[n]` represents the argument at the n position.

5. Packages extend the functionality of python. A great repositories of packages is PyPI (<https://pypi.org/>). Search for a package (of your preferred topic), install it and run a simple demo, preferentially in your favorite IDE (spyder, pycharm, etc). Most of the packages have links to their documentations where you can find some minimal examples to run.
